INTRODUCTION

If one is to correctly use the data presented in this document, it is imperative that the distinction be made between population projections and population forecasts. Population projections are usually defined as mathematical extrapolations of the population distribution or totals of some geographic area (usually a city, county, or state). There can be many population projections made of these areas depending on the mathematical model and the assumptions concerning the future trends of the three basic factors of population change — births, deaths, and migration. However, when the user has settled on a certain model and a certain set of assumptions which will give him a most likely projection total or distribution of the set of projections available, he may then consider this projection to be his forecast of the population for that particular geographic area. It is then apparent from these definitions that all forecasts are population projections but not all projections are forecasts.

The figures presented in this document are considered to be population projections. If one completely understands the model and assumptions used for making these projections, and is also willing to assume that one of these projections will be representative of the most likely population total for the future date given, then, and only then, can these projections be used as population forecasts.

I. HISTORICAL POPULATION TRENDS IN MONTANA

The following outline is only a brief summary of population movement in Montana from 1880 to 1970. For more detailed information, one should consult the sources listed in the bibliography of this report.

PRE-1920's

From statehood to around the 1920's, Montana experienced enormous population growth. Because of heavy net in-migration, primarily due to the opportunities available in agriculture and mining, Montana's population grew from about 39,000 in 1880 to around 549,000 in 1920. While the majority of these new settlers to Montana were U.S. citizens about 34% were foreign born whites seeking new opportunities in the West (see Table 1).

TABLE 1
ESTIMATED NET MIGRATION IN MONTANA

DECADE	ESTIMATED MIGRATION		
	TOTAL*	FOREIGN WHITE	NATIVE WHITE
1880 - 1890	+ 70,600	+ 30,900	+ 39,800
1890 - 1900	+ 63,500	+ 26,400	+ 37,100
1900 - 1910	+ 86,500	+ 35,200	+ 51,000
1910 - 1920	+ 90,100	+ 14,800	+ 75,400
1920 - 1930	- 72,900	- 5,900	- 66,900
1930 - 1940	- 19,300	- 4,400	- 14,800
1940 - 1950	- 42,200	- 500	- 41,900
1950 - 1960	- 25,300	- 1,800	- 23,500
1960 - 1970	- 58,000	- 1,000	- 57,000

Prior to 1920, settlement within Montana was mostly scattered across the eastern half where available land dictated migration, while in the western half of Montana settlement was mostly confined to the mining cities and mountain valleys.

1920's - 1970

With the erosion of farm prices and the decline of mining as a major industry in Montana, more people began leaving than arriving; as a result, Montana began to experience a net out-migration. In fact, from 1920 to 1930, Montana was the only state in which net out-migration actually exceeded natural survival (births minus deaths). Consequently, Montana lost population in this decade — a complete reversal of prior trends. From 1930 to 1950, Montana again lost a significant proportion of its population through a net out-migration (see Table 1). Lack of opportunity, as in the 1920's, was the main cause of this no-growth situation. Most of this exodus was from the eastern or plains part of the state where farm bankruptcy was a way of life.

Several incidents between 1920 and 1970 had a significant impact upon population movement in and out of Montana. The agricultural situation in the 1920's had worsened and many of the earlier settlers in eastern Montana were forced to leave their lands and farms by foreclosure. In 1920, about 59% of the people in Montana lived in the eastern plains with a majority of these, about 77%, classified as rural dwellers. In the same year, about 41% of the state's population resided in the mountainous area, with about 54% classified as rural dwellers. By 1930, about 73,000 net migrants had left the state — almost 1/8 of the state's 1920 population — and the rural population in Montana had dwindled from about 376,000 in 1920 to around 356,000 in 1930. The urban centers of the mountains began the process known as urbanization around the 1920's. In fact, while most

places in Montana were actually losing population, the western urban regions actually gained population during the 1920's.

When the depression and great drought of the 1930's hit Montana, there was an even greater shift towards urbanization. The plains again lost population in this period, while the western region, although apparently experiencing some net out-migration, did grow about 11%. Again the urban population centers in the eastern and western region showed an actual increase in population, while the rural section of the population in eastern Montana continued an already marked decline. These trends continued through the 1940s until, in 1950, the urban-rural difference in population that existed between the plains and the mountains had almost evaporated. What occurred to eastern and western Montana from 1920 to 1970 is only a sample of what happened to the plains and the mountainous areas of the U.S. The eastern area of Montana from 1920 to 1950 underwent an exodus of people like that of the rest of the Great Plains, such as the Dakotas and Nebraska, while the mountainous area of Montana grew in much the same manner as the western sections of Wyoming and Colorado.

From 1950 to 1960, Montana's population, although still being urbanized by the migration of people from farms, was affected primarily by the buildup of the military bases in Cascade and Valley counties. These, together with further urbanization, caused Montana's population to grow from about 591,000 in 1950 to 675,000 in 1960. Although Montana still experienced net out-migration from 1950 to 1960, most of these out-migrants who were between the ages of 18 and 25 were not moving entire families with them. This type of migration was especially true in the 1960's when it is estimated that approximately 50% of the net out-migrants were between the ages of 15 and 24. This, together with the closing of the Glasgow Air Base in Valley County and the decline of mining activity in Silver Bow County, accounted for almost 58,000 net migrants leaving the state during the 1960-1970 decade.

TABLE 2
MONTANA POPULATION BY AGE (NEAREST 1,000)

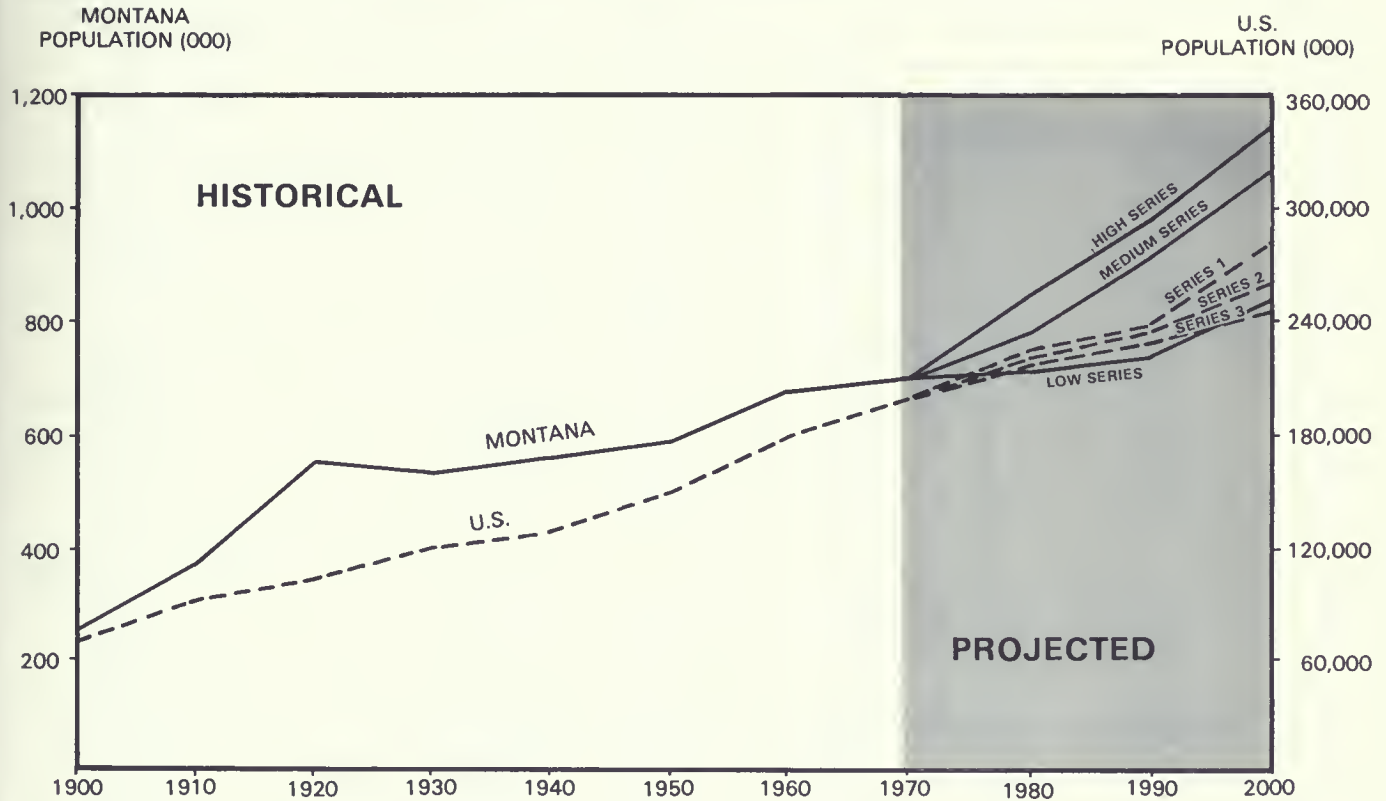

POPULATION	TOTAL	Age Distribution					
		0 - 4	5 - 14	15 - 24	25 - 44	45 - 64	65 +
1880	39,000	4,000	6,000	7,000	17,000	5,000	Z
1890	143,000	13,000	19,000	25,000	57,000	15,000	2,000
1900	243,000	27,000	44,000	41,000	95,000	30,000	5,000
1910	376,000	38,000	64,000	73,000	137,000	52,000	9,000
1920	549,000	67,000	111,000	83,000	185,000	84,000	17,000
1930	538,000	49,000	110,000	94,000	156,000	101,000	27,000
1940	559,000	49,000	93,000	102,000	157,000	122,000	36,000
1950	591,000	68,000	102,000	82,000	170,000	118,000	51,000
1960	675,000	83,000	144,000	90,000	167,000	125,000	65,000
1970	694,000	57,000	151,000	122,000	155,000	141,000	69,000

SOURCE: U.S. Bureau of the Census, *Historical Statistics of the United States, Colonial Times to 1970*, Bicentennial Edition; Part 1, 1975.

The migration trends noted above are further exemplified in Table 2 by the shifts in age distribution of the people in Montana from censal year to censal year. For instance, the 5-14 year old age group in one censal year would be the 15-24 year old age group in the next censal year and one can see that, since the 1920's, there has been a substantial out-migration in each decade. This indicates that once young Montanans graduate from high school, the probability is quite high that they out-migrate from the state. The development of recent migration rates by age and sex for the 1950's and 1960's by the Research and Information Division in the Montana Department of Community Affairs supports this supposition.

Figure 1
MONTANA AND U.S. GROWTH TRENDS
HISTORICAL AND PROJECTED

II. CURRENT AND FUTURE POPULATION TRENDS IN MONTANA

1970 - 1975

Since the early 1970's, Montana has experienced a complete reversal in migration trends and although these trends seem to be weakening, it is expected that the state will continue to show a net in-migration over the next 20 years or so. Since 1970, Montana's total population growth rate has averaged about 1.5% per year, compared with the U.S. average of around 1%. If Montana is examined with respect to its plains vis-a-vis the mountain region, the eastern region appears to be growing at about the same rate as the Dakotas and Nebraska, while the mountainous regions are enjoying a growth rate similar to Colorado, Western Wyoming, and Southern Idaho. From Figure One, one can see that the projections correspond with the 1970-1975 Population Projections of the Bureau of Census. The projected growth rates for Montana and the United States may be found in Table 3.

TABLE 3
PROJECTED GROWTH RATES
MONTANA AND THE U.S.

DECADE	MONTANA SERIES			I	U.S. SERIES*	
	HIGH	MEDIUM	LOW		II	III
1970 - 1980	20.6%	13.3%	2.8%	10.3%	9.3%	8.6%
1980 - 1990	18.4%	16.7%	7.8%	13.7%	9.6%	7.0%
1990 - 2000	16.4%	16.4%	7.1%	11.0%	6.9%	4.0%

* SOURCE: U.S. Bureau of the Census, *Current Population Reports*, Series P-25, No. 704, July, 1977.

These rates indicate that the Medium Series for Montana will continue at a rate somewhat greater than the total U.S. growth rate. As stated in the methodology section, Montana's high and low series were developed based upon past high and low growth patterns. The U.S. series presented in Figure 1 is an update of past population projections in which lower mortality rates were used based upon current mortality trends. The Series I Figures for the U.S. correspond to a 2.7 completed cohort fertility rate compared to the Series II with a completed cohort fertility rate of 2.1 and the Series III with a completed cohort fertility rate of 1.7.

VI. METHODOLOGY

The model used for projecting the population of Montana is primarily a county based variation of the cohort-survival type. This model was developed in the Research and Information Systems Division of the Montana Department of Community Affairs and is the culmination of over two years of research work in population projections.

County Projections

The basic mathematical model for projecting county population by age and sex for each decade is given as:

$$P_{t+10}^{i+10} = P_t^i \times S_{t,t+10}^i + M_{t,t+10}^{i,i+10}$$

where i is a five-year age-sex cohort in a particular county and t is a census year. P is the number of people in the cohort, S is the survival rate (10-year) for this cohort, and M is an estimate of the number of net migrants for this age-sex cohort. As an example, the equation for the number of 10-14 year-old males in any county in 1980 is given as:

$$P_{1980}^{10-14} = P_{1970}^{0-4} \times S_{1970,1980}^{0-4} + M_{1970,1980}^{0-4,10-14}$$

In Montana's case the population was split into Indian and non-Indian categories and then projected separately and summed. To obtain the intercensal projections (1975, 1985, and 1995), interpolation techniques were utilized. The above equation is, of course, valid only for the projected sex cohorts of those aged ten and more. To estimate the 0-4 and 5-9 age-sex cohorts in the projection year fertility rates utilized by the Bureau of Census were adjusted to Montana's Indian and non-Indian populations.

The following summary describes the technique employed to arrive at the projections series displayed in this publication.

A. Projected or Expected Population

The term $P_t^i \times S_{t,t+10}^i$ is sometimes referred to as the 'expected population' of the $i+10$ th age-sex cohort in the $t+10$ th census year for any county. The survival rates used in this model correspond to the projected survival rates by age and sex found in Current Population Reports, *Population Estimates and Projections*, Series P-25, No. 601, published by the Bureau of Census. These rates were adjusted to local differences of Indian and non-Indian populations based on the reported number of deaths in counties in Montana from 1969 to 1971. Using these survival rates, one can obtain an expected population (by sex) for each of the five-year age cohorts aged ten and above for each county.

B Projected Migration

Migration rates, in terms of the expected population of a particular five-year age-sex cohort, were developed for all counties for the 1950-1960 and 1970-1980 decennia using census data and census survival rates which are published by the Bureau of Census. Methodology for developing these estimates can be found in *Current Population Reports* (P-23 series, No. 41) published by the Bureau of Census. After developing migration rates, a cluster analysis was performed on these 112 data points (2 decades, 56 counties) with 28 variables (14 age groups, male and female). The result was the clustering of these rates into three basic groups. On observing the migration rates within these three groups, one could easily attach a descriptive name to each. For example, the first grouping included the migration rates for Beaverhead County (1950-1960 and 1960-1970), Gallatin County (1950-1960 and 1960-1970), and Missoula County (1950-1960 and 1960-1970). On close observation of the migration rates, one could see that total migration in these counties was heavily affected by the universities in each county. This is to say that population change in these counties is mainly affected by the migration of people in the 15-19 year old and 20-24 year old age groups. Similarly, the other two groups could easily be defined as "growth" and "no-growth" counties with the majority (77) of the data points (counties) in the no-growth group. The basic assumption in using these migration rates is that future net migration for any particular county can be estimated by using one of the set of migration rates from the output of the cluster analysis. Once a county was assumed to fit in one of the groups (growth, no-growth, or university type) an average set of migration rates was applied to the expected population of a particular age-sex cohort to arrive at an estimate of projected net migration for that cohort. Three sets (high, low, and medium) of averages computed on the inner- and outer-quartile set of migration rates were developed for each group. A county could then be assumed to be a high,

average, or low level, growth, no growth, or university type county. For example, the medium series for Beaverhead County is based upon the low level type university rates. This was assumed because the other two counties (Gallatin and Missoula) in the university type group have grown at a much faster rate than Beaverhead County. In fact, the medium series for these two counties are high level university type migration rates. All counties were thus fitted into one of the aforementioned three groups and, as stated previously, a high, average, or low level migration rate was used to arrive at the medium series. To compute the high and low series of projections for each county, a multiple of the standard deviation for each particular age-sex cohort migration rate was added or subtracted from the high, average, or low level set of migration rates. The high and low series was also constrained by total growth rates for each of the three groups. The migration rates for 1950-1960 for Valley and Cascade counties were excluded because of the military migration influence on the development of gross migration rates. Furthermore, the people in Cascade County associated with Malmstrom Air Force Base were excluded from the projections series and this group of people were assumed to remain constant in total and distribution throughout the projection interval.

A complete list of the migration levels and groups assumed for each county is illustrated in the appendix, Table 1. The grouping assumed remained constant throughout the projection period while the levels within the groups were expected to converge to the average level by the year 2000.

C. Projected Births

Once the numbers of women age 10-44 were projected to the next censal year and interpolated for the interim year, the fertility rates found in Table 2 in the appendix were applied and the total projected births were distributed by sex. An average number of women was used for each rate with this number being multiplied by five to arrive at the cumulative five-year birth totals. The fertility rates illustrated in Table 2 in the Appendix are derived from the Bureau of Census publication *Current Population Reports*, Series P-25, No. 601, issued in October of 1975. The rates illustrated have a completed cohort fertility rate in the year 2000 of 2.137 for both Indians and non-Indians. This compares with the average 1970 fertility rate of 4.246 for Indians and 1.945 for non-Indians. Traditionally, national fertility rates have been lower than those for both Montana Indians and non-Indians; these trends are expected to continue through the projection period. Since the births were developed from migrated mothers, no migration rates were needed for the final 0-4 and interim 0-4 age groups. However, migration rates developed from past births and expected populations were constructed for the final 5-9 age group and these rates, which depend on the migration group and level, were applied to this cohort.

Incorporated City Projections

The incorporated city projections were developed from the county projections using a weighted average of city growth which depended on the size of the city in relation to the size of the county and past growth patterns of the city. Thus, the projections for the cities should be used with utmost caution, bearing in mind the growth patterns and levels assumed for the counties.

State and Planning Region Projections

The medium series projections published for the state are simply the sum of the projections of the counties. The high and low series were developed from the high and low series for the counties; however, these two series were constrained by past growth patterns and the sum of the county high and low series does not equal the state high and low series. The medium series was the only one published for the planning regions as it would be ludicrous to assume that all counties in any one region would grow at a high or low rate at the same time. The medium series for each planning region is simply the sum of the medium series of the counties within that region.
